## Outline

- Hashing (OWF, Collision Resistance)
- AES
- Linear Algebra Review

## Hashing

## Hash Functions

A Hash Function $H:\{0,1\}^{*} \rightarrow\{0,1\}^{\lambda}$ maps strings from arbitrary length to strings of length $\lambda$

Useful properties for hash functions: collision resistance and one-wayness.

## Applications for Hash Functions

Password Storage: Suppose a server wants to store the passwords of its users. However, we don't want to store the passwords directly.

## Applications for Hash Functions

Password Storage: Suppose a server wants to store the passwords of its users. However, we don't want to store the passwords directly.

- Store $H(p w)$ instead

## Applications for Hash Functions

Password Storage: Suppose a server wants to store the passwords of its users. However, we don't want to store the passwords directly.

- Store $H(p w)$ instead
- When a user logs in, checks that the hash of the input matches the stored hash value.

## Applications for Hash Functions

Password Storage: Suppose a server wants to store the passwords of its users. However, we don't want to store the passwords directly.

- Store $H(p w)$ instead
- When a user logs in, checks that the hash of the input matches the stored hash value.
- Even if an adversary gets the stored hash values, we don't want them to discover the passwords of the users: Use one-way functions!

## One-way Functions

## Intuition

A polynomial time function $H$ is said to be one-way if given $H(x)$ it is difficult to find $x^{\prime}$ such that $H(x)=H\left(x^{\prime}\right)$.

## One-way Functions

## Intuition

A polynomial time function $H$ is said to be one-way if given $H(x)$ it is difficult to find $x^{\prime}$ such that $H(x)=H\left(x^{\prime}\right)$.

## Formal Definition

A polynomial time function $H:\{0,1\}^{*} \rightarrow\{0,1\}^{*}$ is a one-way function (OWF) if for any probabilistic polynomial-time adversary $A$ there exists a negligible function $\mu$ such that for every security parameter $\lambda \in \mathbb{N}$,

$$
\operatorname{Pr}\left[H(x)=H\left(x^{\prime}\right): \begin{array}{c}
x \leftarrow^{\mathrm{R}}\{0,1\}^{\lambda} \\
x^{\prime} \leftarrow A(H(x))
\end{array}\right] \leq \mu(\lambda)
$$

## One-way Functions

## Formal Definition

A polynomial time function $H:\{0,1\}^{*} \rightarrow\{0,1\}^{*}$ is a one-way function (OWF) if for any probabilistic polynomial-time adversary $A$ there exists a negligible function $\mu$ such that for every security parameter $\lambda \in \mathbb{N}$,

$$
\operatorname{Pr}\left[H(x)=H\left(x^{\prime}\right): \begin{array}{c}
x \leftarrow^{\mathrm{R}}\{0,1\}^{\lambda} \\
x^{\prime} \leftarrow A(H(x))
\end{array}\right] \leq \mu(\lambda) .
$$

- $\lambda$ is called the security parameter. The adversary and the function runs polynomial time in $\lambda$

## One-way Functions

## Formal Definition

A polynomial time function $H:\{0,1\}^{*} \rightarrow\{0,1\}^{*}$ is a one-way function (OWF) if for any probabilistic polynomial-time adversary $A$ there exists a negligible function $\mu$ such that for every security parameter $\lambda \in \mathbb{N}$,

$$
\operatorname{Pr}\left[H(x)=H\left(x^{\prime}\right): \begin{array}{c}
x<^{\mathrm{R}}\{0,1\}^{\lambda} \\
x^{\prime} \leftarrow A(H(x))
\end{array}\right] \leq \mu(\lambda)
$$

- $\lambda$ is called the security parameter. The adversary and the function runs polynomial time in $\lambda$
- $\mu$ is a negligible function: for every polynomial $p$, there exists $\lambda_{0}$ such that for every $\lambda>\lambda_{0}, \mu(\lambda)<\frac{1}{p(\lambda)}$

## One-way Functions

## Formal Definition

A polynomial time function $H:\{0,1\}^{*} \rightarrow\{0,1\}^{*}$ is a one-way function (OWF) if for any probabilistic polynomial-time adversary $A$ there exists a negligible function $\mu$ such that for every security parameter $\lambda \in \mathbb{N}$,

$$
\operatorname{Pr}\left[H(x)=H\left(x^{\prime}\right): \begin{array}{c}
x \leftarrow^{\mathrm{R}}\{0,1\}^{\lambda} \\
x^{\prime} \leftarrow A(H(x))
\end{array}\right] \leq \mu(\lambda) .
$$

- $\lambda$ is called the security parameter. The adversary and the function runs polynomial time in $\lambda$
- $\mu$ is a negligible function: for every polynomial $p$, there exists $\lambda_{0}$ such that for every $\lambda>\lambda_{0}, \mu(\lambda)<\frac{1}{p(\lambda)}$
- In practice, negligible is considered less than a very small constant, like $2^{-128}$

## Applications for Hash Functions

Authenticating Files: suppose a user wants to store a large file $F$ on an untrusted server. We want to make sure that the server does not tamper with the file.

## Applications for Hash Functions

Authenticating Files: suppose a user wants to store a large file $F$ on an untrusted server. We want to make sure that the server does not tamper with the file.

- User stores a succinct hash $H(F)$ locally

## Applications for Hash Functions

Authenticating Files: suppose a user wants to store a large file $F$ on an untrusted server. We want to make sure that the server does not tamper with the file.

- User stores a succinct hash $H(F)$ locally
- When the user wants to use the file, it will fetch it from the server and receive $F^{\prime}$

## Applications for Hash Functions

Authenticating Files: suppose a user wants to store a large file $F$ on an untrusted server. We want to make sure that the server does not tamper with the file.

- User stores a succinct hash $H(F)$ locally
- When the user wants to use the file, it will fetch it from the server and receive $F^{\prime}$
- User can ensure integrity by checking if $H(F)=H\left(F^{\prime}\right)$ : Need collision resistance!

## Collision Resistance

## Intuition

A hash function $H$ is said to be collision resistant if it is hard to find $x, x^{\prime}$ such that $x \neq x^{\prime}$ and $H(x)=H\left(x^{\prime}\right)$

## Collision Resistance

## Intuition

A hash function $H$ is said to be collision resistant if it is hard to find $x, x^{\prime}$ such that $x \neq x^{\prime}$ and $H(x)=H\left(x^{\prime}\right)$

## Formal Definition

A family of functions $\left\{H_{\lambda}\right\}_{\lambda \in \mathbb{N}}$ where $H_{\lambda}:\{0,1\}^{*} \rightarrow\{0,1\}^{\lambda}$ is said to be collision resistant if for all polynomial-time adversaries $A$ there exists a negligible function $\mu$ such that for every $\lambda \in \mathbb{N}$,

$$
\operatorname{Pr}\left[H_{\lambda}(x)=H_{\lambda}\left(x^{\prime}\right) \wedge x \neq x^{\prime}:\left(x, x^{\prime}\right) \leftarrow A\left(1^{\lambda}\right)\right] \leq \mu(\lambda)
$$

## Sample Problems

Let $f:\{0,1\}^{n} \rightarrow\{0,1\}^{\lambda}$ be a OWF. Define $g:\{0,1\}^{n+1} \rightarrow\{0,1\}^{\lambda}$ to be $g(x)=f(x[0: n])$. Is $g$ a OWF?

## Sample Problems

Let $f:\{0,1\}^{n} \rightarrow\{0,1\}^{\lambda}$ be a OWF. Define $g:\{0,1\}^{n+1} \rightarrow\{0,1\}^{\lambda}$ to be $g(x)=f(x[0: n])$. Is $g$ a OWF?
Solution: This is a OWF. Suppose for contradiction that a PPT adversary could invert $y=g(x)$ with non-negligible probability and obtain $x^{\prime}$ such that $g\left(x^{\prime}\right)=y$. Then, the adversary would be able to invert $f$ by simply taking $x^{\prime}[0: n-1]$. This contradicts the fact that $f$ is a OWF.

## Sample Problems

Let $f:\{0,1\}^{n} \rightarrow\{0,1\}^{\lambda}$ be a OWF. Let $g:\{0,1\}^{2 n} \rightarrow\{0,1\}^{\lambda}$ where $g\left(x_{1} \| x_{2}\right)=f\left(x_{1}\right) \oplus x_{2}$. Does this imply that $g$ is a OWF?

## Sample Problems

Let $f:\{0,1\}^{n} \rightarrow\{0,1\}^{\lambda}$ be a OWF. Let $g:\{0,1\}^{2 n} \rightarrow\{0,1\}^{\lambda}$ where $g\left(x_{1} \| x_{2}\right)=f\left(x_{1}\right) \oplus x_{2}$. Does this imply that $g$ is a OWF?
Solution: No. Suppose we are given $y=g\left(x_{1} \| x_{2}\right)$. Then, let us choose a random $x_{1}^{\prime}$ and compute $f\left(x_{1}^{\prime}\right)$. Then, let us choose $x_{2}^{\prime}=y \oplus f\left(x_{1}^{\prime}\right)$. We get that $g\left(x_{1}^{\prime} \| x_{2}^{\prime}\right)=f\left(x_{1}^{\prime}\right) \oplus y \oplus f\left(x_{1}^{\prime}\right)=y$.

## Sample Problems

Suppose that $h_{1}:\{0,1\}^{n} \rightarrow\{0,1\}^{d}$ is a collision resistant hash function. Does it imply that $h_{2}:\{0,1\}^{n-d} \times\{0,1\}^{n} \rightarrow\{0,1\}^{d}$ is also collision resistant, where $h_{2}(x, y)=h_{1}\left(x \| h_{1}(y)\right)$ ?

## Sample Problems

Suppose that $h_{1}:\{0,1\}^{n} \rightarrow\{0,1\}^{d}$ is a collision resistant hash function. Does it imply that $h_{2}:\{0,1\}^{n-d} \times\{0,1\}^{n} \rightarrow\{0,1\}^{d}$ is also collision resistant, where $h_{2}(x, y)=h_{1}\left(x \| h_{1}(y)\right)$ ?
Solution: Yes. Suppose $h_{2}$ is not collision resistant, so we are able to find $x, y, x^{\prime}, y^{\prime}$ such that $(x, y) \neq\left(x^{\prime}, y^{\prime}\right)$ and $h_{2}(x, y)=h_{2}\left(x^{\prime}, y^{\prime}\right)$. Therefore, either it is the case that $x\left\|h_{1}(y)=x^{\prime}\right\| h_{1}\left(y^{\prime}\right)$ or $x\left\|h_{1}(y) \neq x^{\prime}\right\| h_{1}\left(y^{\prime}\right)$. In the first case, that implies that $h_{1}(y) \neq h_{1}\left(y^{\prime}\right)$, so we have found a collision for $h_{1}$. In the second case, $x \| h_{1}(y)$ and $x^{\prime} \| h_{1}\left(y^{\prime}\right)$ cause a collision.

## AES

AES is a pseudorandom permutation.

## Pseudorandom Function

A function $f: K \times\{0,1\}^{\lambda} \rightarrow\{0,1\}^{\lambda}$ is said to be a pseudorandom function (PRF) if a probabilistic polynomial time adversary $A$ cannot distinguish between given oracle access to $f(k, \cdot)$ for random $k \leftarrow K$ and oracle access to a truly random function $U:\{0,1\}^{\lambda} \rightarrow\{0,1\}^{\lambda}$ :
For all ppt adversaries $A$, there exists negligible $\mu$ such that

$$
\left|\operatorname{Pr}\left[A^{f(k, \cdot)}\left(1^{\lambda}\right)=1: k \leftarrow^{\mathbb{R}} K\right]-\operatorname{Pr}\left[A^{U}\left(1^{\lambda}\right)=1: U \mathbb{R}^{\mathbb{R}} \operatorname{Fun}_{\lambda \rightarrow \lambda}\right]\right| \leq \mu(\lambda) .
$$

## AES

## Pseudorandom Permutation

A function $f: K \times\{0,1\}^{\lambda} \rightarrow\{0,1\}^{\lambda}$ is said to be a pseudorandom permutation (PRP) if a probabilistic polynomial time adversary $A$ cannot distinguish between given oracle access to $f(k, \cdot)$ for random $k \leftarrow K$ and oracle access to a truly random permutation $U:\{0,1\}^{\lambda} \rightarrow\{0,1\}^{\lambda}$, AND $f$ maps distinct inputs to distinct outputs and there exists an efficient inversion algorithm $f^{-1}(k, \cdot)$.

## AES

## Pseudorandom Permutation

A function $f: K \times\{0,1\}^{\lambda} \rightarrow\{0,1\}^{\lambda}$ is said to be a pseudorandom permutation (PRP) if a probabilistic polynomial time adversary $A$ cannot distinguish between given oracle access to $f(k, \cdot)$ for random $k \leftarrow K$ and oracle access to a truly random permutation $U:\{0,1\}^{\lambda} \rightarrow\{0,1\}^{\lambda}$, AND $f$ maps distinct inputs to distinct outputs and there exists an efficient inversion algorithm $f^{-1}(k, \cdot)$.

## PRP/PRF Switching Lemma

If the adversary queries for $T$ input/output pairs, then the probability that it can distinguish between a PRP and a PRF is at most $\frac{T(T-1)}{2^{\lambda+1}}$

## AES

$\operatorname{AES}(k, x)$ :

$k_{0}, \ldots, k_{10}$ are derived from the key $k$ through an invertible algorithm. $\pi$ is an invertible function consisting of 3 steps: substitute bytes, shift rows, and mix columns (no mix columns in the last round)

## AES Steps

## AES treats its inputs as a matrix of bytes.

## AES Steps

AES treats its inputs as a matrix of bytes.
Substitute bytes: Replaces bytes in the matrix according to a map called the sbox. This adds nonlinearity to the algorithm (the other two steps are linear).
right (low-order) nibble

## AES Steps

Shift rows: Cyclically shifts the bytes in each row by a certain offset. The first row is left unchanged, the second row is shifted one to the left, the third row is shifted two, and the fourth row is shifted three.

| $\begin{gathered} \text { No } \\ \text { change } \end{gathered}$ | $a_{0,0}$ | $a_{0,1}$ | $\mathrm{a}_{0,2}$ | $\mathrm{a}_{0,3}$ |

## AES Steps

Mix columns: Each column is multiplied with a specific matrix

## Linear Algebra Review: Solving $\mathbf{A x}=\mathbf{b}$

## Linear Algebra Review: Solving $\mathbf{A x}=\mathbf{b}$

We can solve $A \mathbf{x}=\mathbf{b}$ by using Gaussian elimination to put the matrix in row echelon form.

$$
\left[\begin{array}{rrrrr}
1 & 2 & 2 & 2 & b_{1} \\
2 & 4 & 6 & 8 & b_{2} \\
3 & 6 & 8 & 10 & b_{3}
\end{array}\right] \rightarrow \cdots \rightarrow\left[\begin{array}{lllll}
1 & 2 & 2 & 2 & b_{1} \\
0 & 0 & 2 & 4 & b_{2}-2 b_{1} \\
0 & 0 & 0 & 0 & b_{3}-b_{2}-b_{1}
\end{array}\right]
$$

## Linear Algebra Review: Solving $\mathbf{A x}=\mathbf{b}$

We can solve $A \mathbf{x}=\mathbf{b}$ by using Gaussian elimination to put the matrix in row echelon form.
$\left[\begin{array}{rrrrr}1 & 2 & 2 & 2 & b_{1} \\ 2 & 4 & 6 & 8 & b_{2} \\ 3 & 6 & 8 & 10 & b_{3}\end{array}\right] \rightarrow \cdots \rightarrow\left[\begin{array}{lllll}1 & 2 & 2 & 2 & b_{1} \\ 0 & 0 & 2 & 4 & b_{2}-2 b_{1} \\ 0 & 0 & 0 & 0 & b_{3}-b_{2}-b_{1}\end{array}\right]$

- We can then get a particular solution using back-substitution, setting all free variables to 0 : Let $\mathbf{b}=(1,5,6)$, then $\mathbf{x}_{p}=(-2,0,3 / 2,0)$

## Linear Algebra Review: Solving $\mathbf{A x}=\mathbf{b}$

We can solve $A \mathbf{x}=\mathbf{b}$ by using Gaussian elimination to put the matrix in row echelon form.

$$
\left[\begin{array}{rrrrr}
1 & 2 & 2 & 2 & b_{1} \\
2 & 4 & 6 & 8 & b_{2} \\
3 & 6 & 8 & 10 & b_{3}
\end{array}\right] \rightarrow \cdots \rightarrow\left[\begin{array}{lllll}
1 & 2 & 2 & 2 & b_{1} \\
0 & 0 & 2 & 4 & b_{2}-2 b_{1} \\
0 & 0 & 0 & 0 & b_{3}-b_{2}-b_{1}
\end{array}\right]
$$

- We can then get a particular solution using back-substitution, setting all free variables to 0 : Let $\mathbf{b}=(1,5,6)$, then $\mathbf{x}_{p}=(-2,0,3 / 2,0)$
- To get the complete solution, we add the nullspace (solutions to $A \mathbf{x}=\mathbf{0}): \mathbf{x}=(-2,0,3 / 2,0)+c_{1}(-2,1,0,0)+c_{2}(2,0,-2,1)$

## Linear Algebra Review: Solving $A x=b$

How many solutions are there?
