A Method for Obtaining Digital Signatures and Public- Key Cryptosystems

R. L. Rivest, A. Shamir, and L. Adleman
MIT Laboratory for Computer Science
and Department of Mathematics

An encryption method is presented with the novel property that publicly revealing an encryption key does not thereby reveal the corresponding decryption key. This has two important consequences:

- (1) Creation or other secure means are not needed to transmit keys, since a message can be encrypted using an encryption key publicly revealed by the intended recipient. Only he can decipher the message, since only he knows the corresponding decryption key.
- (2) A message can be "signed" using a privately held decryption key. Anyone can verify this signature using the corresponding publicly revealed encryption key. Signatures cannot be forged, and a signer cannot later deny the validity of his signature. This has obvious applications in "electronic mail" and "electronic funds transfer" systems. A message is encrypted by representing it as a number M , raising M to a publicly specified power e , and then taking the remainder when the result is divided by the publicly specified product, n , of two large secret prime numbers p and q . Decryption is similar, only a different, secret, power d is used, where $e \cdot d = 1 \pmod{(p-1)(q-1)}$. The security of the system rests in part on the difficulty of factoring the published divisor, n .

Key Words and Phrases: digital signatures, public-key cryptosystems, privacy, authentication, security, factoring, prime number, electronic mail, message-passing, electronic funds transfer, cryptography.

I. Introduction

The era of "electronic mail" [10] may seem be upon us; we must ensure that two important properties of the current "paper mail" system are preserved: (a) messages are private, and (b) messages can be signed. We demonstrate in this paper how to build these capabilities into an electronic mail system.

At the heart of our proposal is a new encryption method. This method provides an implementation of a "public-key cryptosystem," an elegant concept invented by Diffie and Hellman [1]. Their article motivated our research, since they presented the concept but not any practical implementation of such a system. Readers familiar with [1] may wish to skip directly to Section V for a description of our method.

II. Public-Key Cryptosystems

In a "public-key cryptosystem" each user places in a public file an encryption procedure E . That is, the public file is a directory giving the encryption procedure of each user. The user keeps secret the details of his corresponding decryption procedure D . These procedures have the following four properties:

- (1) Deciphering the enciphered form of a message M yields M . Formally,
 $D(E(M)) = M$.
- (2) Both E and D are easy to compute.
- (3) By publicly revealing E the user does not reveal an easy way to compute D . This means that in practice only he can decipher messages enciphered with E , or compute D efficiently.
- (4) If a message M is first deciphered and then enciphered, M is the result. Formally,
 $E(D(M)) = M$.

An encryption (or decryption) procedure typically consists of a general method and an encryption key. The general method, which controls the key, enciphers a message M to obtain the enciphered form of the message, called the ciphertext C . Everyone can use the same general method; the security of a given procedure will rest on the security of the key. Revealing an encryption algorithm thus means revealing the key.

When the user reveals E he reveals a very inefficient method of computing $D(C)$, testing all possible messages M until one such that $E(M) = C$ is found. If property (3) is satisfied the number of such messages to test will be so large that this approach is impractical.

A function E satisfying (a)-(c) is a "trap-door one-way function"; if it also satisfies (d) it is a "trap-door one-way permutation." Diffie and Hellman [1] introduced the concept of trap-door one-way functions but

ABSTRACT			
[57] A cryptographic communications system and method. The system includes a communications channel coupled to at least one terminal having an encoding device and to at least one terminal having a decoding device. A message-to-be-transferred is enciphered to ciphertext at the encoding terminal by first encoding the message as a number M in a predetermined set, and then raising that number to a first predetermined power (associated with the intended receiver) and finally computing the remainder, or residue, C, when the exponentiated number is divided by the product of two predetermined prime numbers (associated with the intended receiver). The residue C is the ciphertext. The ciphertext is deciphered to the original message at the decoding terminal in a similar manner by raising the ciphertext to a second predetermined power (associated with the intended receiver), and then computing the residue, M', when the exponentiated ciphertext is divided by the product of the two predetermined prime numbers associated with the intended receiver. The residue M' corresponds to the original encoded message M.

Conclusions

U.S. cryptography policy evolves

- ▶ U.S. government initially tried to control and limit public-sector research and use of cryptography
- ▶ Attempt to chill research via ITAR (1977)
- ▶ MIT “Changing Nature of Information” Committee (1981; Dertouzos, Low, Rosenblith, Deutch, Rivest,...)

MIT Committee Seeks Cryptography Policy

Questions of who should do research on cryptography and how results should be disseminated are the first order of business

Within the next 10 years, networks consisting of tens of thousands of computers will connect businesses, corporations and homes in ways that make communications for individuals and for society if computers continue to be connected, as they are now, according to local decisions by individuals and organizations. It will be easy to send computer programs between connected machines and to instruct a program to search for, select,

Factoring Records

Factoring on a Quantum Computer?

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$$

$$|\alpha|^2 + |\beta|^2 = 1$$

=

$$\alpha|0\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

+

$$\beta|1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

In 1994, Peter Shor invented a fast factorization algorithm that runs on a (hypothetical) *quantum computer* and works by determining multiplicative period of elements mod n .

- ▶ Dark clouds on horizon for RSA?

Hash Function Attacks

- ▶ In 2004 Xiaoyun Wang and colleagues found a way to produce *collisions* for MD5:

$$\text{MD5}(\textit{file1}) = \text{MD5}(\textit{file2}) \quad !!!$$

Also for SHA-1 and many other hash functions.
Major break!!

Hash Function Attacks

- ▶ In 2004 Xiaoyun Wang and colleagues found a way to produce *collisions* for MD5:

$$\text{MD5}(\textit{file1}) = \text{MD5}(\textit{file2}) \quad !!!$$

Also for SHA-1 and many other hash functions.
Major break!!

- ▶ So NIST ran a competition for new hash function standard (SHA-3 = Keccak).

Zero-Knowledge Proofs

Zero-Knowledge Proofs

I can convince you

Zero-Knowledge Proofs

*I can convince you
I know a solution
to a hard problem*

Zero-Knowledge Proofs

*I can convince you
I know a solution
to a hard problem
while telling you nothing
about my solution*

Zero-Knowledge Proofs

*I can convince you
I know a solution
to a hard problem
while telling you nothing
about my solution
even if you are very skeptical!*

*Goldwasser, Micali, Rackoff (1985)
Goldreich, Micali, Wigderson (1986)*

Zero-Knowledge Proofs

*I can convince you
I know a solution
to a hard problem
while telling you nothing
about my solution
even if you are very skeptical!*

*Goldwasser, Micali, Rackoff (1985)
Goldreich, Micali, Wigderson (1986)*

An enormously useful capability!

Payment Systems

- ▶ *Probabilistic payments* (Micali and Rivest, 2001).
“Peppercoin” payments. Paying you ten cents is like paying you one dollar with probability $1/10$.

Payment Systems

- ▶ *Probabilistic payments* (Micali and Rivest, 2001). “Peppercoin” payments. Paying you ten cents is like paying you one dollar with probability $1/10$.
- ▶ *Bitcoin* (Nakamoto, 2009). The “blockchain” for decentralized consensus.

Payment Systems

- ▶ *Probabilistic payments* (Micali and Rivest, 2001). “Peppercoin” payments. Paying you ten cents is like paying you one dollar with probability $1/10$.
- ▶ *Bitcoin* (Nakamoto, 2009). The “blockchain” for decentralized consensus.
- ▶ Ethereum, Dogecoin, Litecoin, Zero-cash, ...

Voting Systems

New “end-to-end” cryptographic voting systems (Chaum, Neff, Benaloh, Ryan, Rivest, Adida, ...):

- ▶ all ballots posted on web (encrypted)
- ▶ voters verify their votes are correct (while preventing vote-selling and coercion)
- ▶ anyone can verify final tally
- ▶ may be done with paper ballots

Cryptography *increases* transparency and verifiability!

Fully Homomorphic Encryption

- ▶ In 1978, Rivest, Adleman, and Dertouzos asked, *“Can one compute on encrypted data, while keeping it encrypted?”*

Fully Homomorphic Encryption

?

!

- ▶ In 1978, Rivest, Adleman, and Dertouzos asked, *“Can one compute on encrypted data, while keeping it encrypted?”*
- ▶ In 2009, Craig Gentry (Stanford, IBM) gave solution based on use of lattices. If efficiency can be greatly improved, could be huge implications (e.g. for cloud computing).
